(57) Abstract: Non-peptide GnRH agents capable of inhibiting the effect of gonadotropin-releasing hormone are described. Such compounds and their pharmaceutically acceptable salts, prodrugs, and active metabolites are suitable for treating mammalian reproductive disorders and steroid hormone-dependent tumors as well as for regulating fertility, where suppression of gonadotropin release is indicated. Methods for synthesizing the compounds and intermediates useful in their preparation are also described.

**TECHNICAL FIELD AND INDUSTRIAL APPLICABILITY  
OF THE INVENTION**

This invention relates generally to compounds that affect the action of human gonadotropin-releasing hormone (GnRH). More particularly, it relates to non-peptide GnRH antagonists or agonists and to their preparation. These non-peptide GnRH agents have advantageous physical, chemical, and biological properties, and are useful medicaments for diseases or conditions mediated by modulation of the pituitary-gonadal axis. The invention also relates to methods for treating individuals needing therapeutic regulation of GnRH--i.e., methods for treating diseases and conditions mediated by GnRH regulation. The invention further relates to processes for synthesizing intermediate compounds useful for making GnRH agents.

**BACKGROUND OF THE INVENTION**

Gonadotropin-Releasing Hormone (GnRH), also known as luteinizing hormone-releasing hormone (LH-RH), plays a central role in the biology of reproduction. A large variety of analogs have been used for an increasing number of clinical indications. The GnRH decapeptide (pyro-Glu-His-Trp-Ser-Tyr-Gly-Leu-Arg-Pro-Gly-NH<sub>2</sub> or p-EHWSYGLRPG-NH<sub>2</sub>) is produced in neurons of the medial basal hypothalamus from a larger precursor by enzymatic processing. The decapeptide is released in a pulsatile manner into the pituitary portal circulation system where GnRH interacts with high-affinity receptors (7-Transmembrane G-Protein Coupled Receptors) in the anterior pituitary gland located at the base of the brain. In the pituitary, GnRH triggers the release of two gonadotropic hormones (gonadotropins): luteinizing hormone (LH) and follicle-stimulating hormone (FSH). In testes and ovaries, LH stimulates the production of testosterone and estradiol, respectively. FSH stimulates follicle growth in women and sperm formation in men. When correctly functioning, the pulse-timed release and concentration levels of GnRH are critical for the maintenance of gonadal steroidogenesis and for normal functions of reproduction related to growth and sexual development.

The pituitary response to GnRH varies greatly throughout life. GnRH and the gonadotropins first appear in the fetus at about ten weeks of gestation. The sensitivity to GnRH declines, after a brief rise during the first three months after birth, until the onset of puberty. Before puberty, the FSH response to GnRH is greater than that of LH. Once puberty begins, sensitivity to GnRH increases, and pulsatile LH secretion ensues. Later in puberty and throughout the reproductive years, pulsatile release of GnRH occurs throughout the day, with LH responsiveness being greater than that of FSH. Pulsatile GnRH release results in pulsatile LH and FSH release from the pituitary, and hence, estrogen and estradiol release from the gonads. After 10 menopause, FSH and LH concentrations rise, and post-menopausal FSH levels are higher than those of LH.

Chronic administration of GnRH agonists and antagonists to animals or to man results in decreased circulating levels of both LH and FSH. GnRH agonists are compounds that mimic endogenous GnRH to stimulate receptors on the pituitary gland, resulting in release of LH and FSH. After a transient rise in gonadal hormone production or "flare" response, chronic administration of GnRH agonists results in a down-regulation of GnRH receptors. GnRH receptor down-regulation and desensitization of the pituitary results in a decrease of circulating levels of LH and FSH. In spite of the symptom-exacerbating hormonal flare experienced, GnRH agonists have been the treatment of choice for sex-steroid-dependent pathophysiologies. For example, GnRH agonists have been used to reduce testosterone production, thereby reducing prostate volume in benign prostatic hyperplasia (BPH) and slowing tumor growth in prostate cancer. These compounds have also been used to treat breast and ovarian cancers.

Recently, GnRH antagonists have become available for clinical evaluation. GnRH antagonists have an immediate effect on the pituitary without the observed flare associated with agonists. Use of GnRH antagonists (usually decapeptides) has been reported in the literature for treatment of breast, ovarian, and prostatic cancers. Other uses of antagonists, like agonists, include endometriosis (including 30 endometriosis with pain), uterine myoma, ovarian and mammary cystic diseases (including polycystic ovarian disease), prostatic hypertrophy, amenorrhea (e.g., secondary amenorrhea), and precocious puberty. These compounds may also be useful in the symptomatic relief of premenstrual syndrome (PMS). Furthermore, antagonists may be useful to regulate the secretion of gonadotropins in male mammals

to arrest spermatogenesis (e.g., as male contraceptives), and for treatment of male sex offenders. Importantly, GnRH antagonists (and agonists) have found utility in treatments where a reversible suppression of the pituitary-gonadal axis is desired.

For over fifty years, androgen deprivation has been the most effective systematic therapy for the treatment of metastatic carcinoma of the prostate. The rationale is simple—the prostate gland requires androgens for proper growth, maintenance, and function. Yet, prostate cancer and benign prostate hyperplasia are common in men and develop in an environment of continuous androgen exposure. Thus, utilizing a GnRH antagonist to interrupt the pituitary-gonadal axis reduces androgen production and results in tumor growth modulation. Furthermore, GnRH antagonists may have a direct effect on tumor growth by blocking receptors on the tumor cells. For those cancer types that respond both to sex hormones and to GnRH directly, antagonists should be effective in slowing tumor growth by these two mechanisms. Since GnRH receptors are present on many prostate and breast cancer cells, it has recently been speculated that GnRH antagonists may also be effective in treating non-hormone-dependent tumors. Recent literature examples indicate that GnRH receptors are present on a number of cancer cell lines, including:

- prostate cancer: GnRH agonists exert both *in vitro*, and *in vivo*, a direct inhibitory action on the growth of both androgen-dependent (LNCaP) and androgen-independent (DU 145) human prostatic cancer cell lines [Montagnani et al., *Arch. Ital. Urol. Androl.*, 69(4), 257-263 (1997); “GnRH Antagonist Inhibit the Growth of Androgen-Independent PC-3 Prostate Cancer in Nude Mice,” Jungwirth et al., *Prostate*, 32(3), 164-172 (1997)];
- ovarian cancer: The demonstration of GnRH receptors in human ovarian cancers provides a rationale for the use of therapeutic approaches based on GnRH analogues in this malignancy [Srkalovic et al., *Int. J. Oncol.*, 12(3), 489-498 (1998)].
- breast cancer: Breast cancer is the most common type of cancer in women over the age of forty and is the leading cause of cancer-related death in women. Systematic endocrine intervention represents a major treatment option for the management of advanced breast cancer, especially with estrogen-dependent cancers. The genes for gonadotropin-releasing hormone

and its receptor are expressed in human breast with fibrocystic disease and cancer [Kottler et al., *Int. J. Cancer*, 71(4), 595-599 (1997)].

GnRH agents may also be useful in treating cancer through generation of thymus re-growth and therefore induction of the development of new T-cells. See  
5 Norwood Abbey press release dated March 5, 2001. These white blood cells, which develop in the thymus gland, are a fundamental component of the immune system's involvement in a range of diseases, including viral infections, transplant organ rejection, cancer, and autoimmune diseases. Thus, for example, since the human immunodeficiency virus (HIV) preferentially infects and destroys T-cells, GnRH  
10 agents may be useful for treating HIV infection or acquired immune deficiency syndrome (AIDS). Additionally, GnRH agents may be useful in combating infection in tissue-transplant patients where immunosuppressive drugs, which remove T-cells, are being administered to counteract rejection of the transplanted tissue. Similarly,  
15 since adequate and effective T-cells help defend against cancer, and chemotherapy and radiation regimens detrimentally impact T-cells, GnRH agents may be useful in treating cancer. Furthermore, GnRH agents may be useful for treating autoimmune diseases such as multiple sclerosis (MS), where T-cells are produced that react against a molecule surrounding nerve cells.

Heretofore, available GnRH antagonists have primarily been peptide analogs  
20 of GnRH. See, e.g., International Publication Nos. WO 93/03058, WO 99/50276, WO 00/12521, and WO 00/12522; Koppan et al., *Prostate*, 38(2), 151-8 (1999); and Nagy et al., *Proc Natl Acad Sci USA*, 97(2), 829-34 (2000). Though peptide antagonists of peptide hormones are often quite potent, the use of peptide antagonists is typically associated with problems because peptides are degraded by physiological  
25 enzymes and often poorly distributed within the organism being treated.

The first non-peptide antagonist of the human leuteinizing hormone-releasing hormone (LHRH) receptor was reported by Cho et al. (*J Med Chem*, 41(22), 4190 (1998). Since then, other non-peptide GnRH antagonists have been reported in the literature. For example, quinolone-6-carboxamides were reported by Walsh et al. in  
30 *Bioorg & Med Chem Ltrs.*, 10, 443-447 (2000). Tricyclic diazepines and cyclic pentapeptides were reported in International Publication Nos. WO 96/38438 and WO 96/34012, respectively. Tetrahydroisoquinoline derivatives were reported in U.S. Patent No. 5,981,521. For additional examples of non-peptide GnRH antagonists, see International Publication Nos. WO 97/21435, WO 97/21703, WO 97/21704, WO

97/21707, WO 99/44987, WO 00/04013, WO 00/12522, WO 00/12521, WO 00/04013, and WO 00/20358.

Despite recent advances, there continues to be a need for non-peptide antagonists of the peptide hormone GnRH with desirable properties. For example,

5 there is a need for non-peptide GnRH agents having advantageous physical, chemical and biological properties compared to peptides, which are useful medicaments for treating diseases mediated via the pituitary-gonadal axis and by directly targeting the receptor on tumor cells. There is also a need for GnRH agents that act upon these receptors to treat both hormone-dependent and hormone-independent cancers.

10 It is understood that while a compound may exhibit the phenomenon of tautomerism, the formula drawings within this specification expressly depict only one of the possible tautomeric forms. It is therefore to be understood that a formula is intended to represent any tautomeric form of the depicted compound and is not to be limited merely to a specific compound form depicted by the structural formula.

15 It is also understood that a compound of Formula I, II or III may exist as an "E" or "Z" configurational isomer, or a mixture of E and Z isomers. It is therefore to be understood that a formula is intended to represent any configurational form of the depicted compound and is not to be limited merely to a specific compound form depicted by the formula drawings.

20 Some of the inventive compounds may exist as single stereoisomers (i.e., essentially free of other stereoisomers), racemates, and/or mixtures of enantiomers and/or diastereomers. All such single stereoisomers, racemates and mixtures thereof are intended to be within the scope of the present invention. In one preferred embodiment, the inventive compounds that are optically active are used in optically pure form.

25 As generally understood by those skilled in the art, an optically pure compound having one chiral center (i.e., one asymmetric carbon atom) is one that consists essentially of one of the two possible enantiomers (i.e., is enantiomerically pure), and an optically pure compound having more than one chiral center is one that is both diastereomerically pure and enantiomerically pure. Preferably, the compounds of the present invention are used in a form that is at least 90% optically pure, that is, a 30 form that contains at least 90% of a single isomer (80% enantiomeric excess ("e.e.") or diastereomeric excess ("d.e.")), more preferably at least 95% (90% e.e. or d.e.), even more preferably at least 97.5% (95% e.e. or d.e.), and most preferably at least 99% (98% e.e. or d.e.).

As indicated above, GnRH agents in accordance with the invention also include active tautomeric and stereoisomeric forms of the compounds of Formula I, II or III, which may be readily obtained using techniques known in the art. For example, optically active (R) and (S) isomers may be prepared via a stereospecific synthesis, e.g., using chiral synthons and chiral reagents, or racemic mixtures may be resolved using conventional techniques.

Additionally, Formulas I, II, and III are intended to cover, where applicable, solvated as well as unsolvated forms of the compounds. Thus, each formula includes compounds having the indicated structure, including the hydrated as well as the non-hydrated forms.

In addition to compounds of the Formulas I, II, and III, the GnRH agents of the invention include pharmaceutically acceptable salts, prodrugs, and active metabolites of such compounds, and pharmaceutically acceptable salts of such metabolites. Such non-peptide agents are pharmaceutically advantageous over peptide agents since they provide better biodistribution and tolerance to degradation by physiological enzymes.

A "prodrug" is a compound that may be converted under physiological conditions or by solvolysis to the specified compound or to a pharmaceutically acceptable salt of such compound. An "active metabolite" is a pharmacologically active product produced through metabolism in the body of a specified compound or salt thereof. Prodrugs and active metabolites of a compound may be identified using routine techniques known in the art. See, e.g., Bertolini et al., *J. Med. Chem.*, 40, 2011-2016 (1997); Shan et al., *J. Pharm. Sci.*, 86 (7), 765-767; Bagshawe, *Drug Dev. Res.*, 34, 220-230 (1995); Bodor, *Advances in Drug Res.*, 13, 224-331 (1984); Bundgaard, *Design of Prodrugs* (Elsevier Press 1985); and Larsen, *Design and Application of Prodrugs*, *Drug Design and Development* (Krosgaard-Larsen et al. eds., Harwood Academic Publishers, 1991); Dear et al., *J. Chromatogr. B*, 748, 281-293 (2000); Spraul et al., *J. Pharmaceutical & Biomedical Analysis*, Vol. 3, No. 2, 103-112 (1992).

The term "pharmaceutically acceptable salts" refers to salt forms that are pharmacologically acceptable and substantially non-toxic to the subject being administered the GnRH agent. Pharmaceutically acceptable salts include conventional acid-addition salts or base-addition salts formed from suitable non-toxic organic or inorganic acids or inorganic bases. Exemplary acid-addition salts include

those derived from inorganic acids such as hydrochloric acid, hydrobromic acid, hydroiodic acid, sulfuric acid, sulfamic acid, phosphoric acid, and nitric acid, and those derived from organic acids such as p-toluenesulfonic acid, methanesulfonic acid, ethane-disulfonic acid, isethionic acid, oxalic acid, p-bromophenylsulfonic acid,  
5 carbonic acid, succinic acid, citric acid, benzoic acid, 2-acetoxybenzoic acid, acetic acid, phenylacetic acid, propionic acid, glycolic acid, stearic acid, lactic acid, malic acid, tartaric acid, ascorbic acid, maleic acid, hydroxymaleic acid, glutamic acid, salicylic acid, sulfanilic acid, and fumaric acid. Exemplary base-addition salts include those derived from ammonium hydroxides (e.g., a quaternary ammonium hydroxide  
10 such as tetramethylammonium hydroxide), those derived from inorganic bases such as alkali or alkaline earth-metal (e.g., sodium, potassium, lithium, calcium, or magnesium) hydroxides, and those derived from organic bases such as amines, benzylamines, piperidines, and pyrrolidines.

If the inventive compound is a base, the desired pharmaceutically acceptable  
15 salt may be prepared by any suitable method available in the art, for example, treatment of the free base with an inorganic acid, such as hydrochloric acid, hydrobromic acid, sulfuric acid, nitric acid, phosphoric acid and the like, or with an organic acid, such as acetic acid, maleic acid, succinic acid, mandelic acid, fumaric acid, malonic acid, pyruvic acid, oxalic acid, glycolic acid, salicylic acid, a  
20 pyranosidyl acid, such as glucuronic acid or galacturonic acid, an alpha-hydroxy acid, such as citric acid or tartaric acid, an amino acid, such as aspartic acid or glutamic acid, an aromatic acid, such as benzoic acid or cinnamic acid, a sulfonic acid, such as p-toluenesulfonic acid or ethanesulfonic acid, or the like.

If the inventive compound is an acid, the desired pharmaceutically acceptable  
25 salt may be prepared by any suitable method, for example, treatment of the free acid with an inorganic or organic base, such as an amine (primary, secondary or tertiary), an alkali metal hydroxide or alkaline earth metal hydroxide, or the like. Illustrative examples of suitable salts include organic salts derived from amino acids, such as glycine and arginine, ammonia, primary, secondary, and tertiary amines, and cyclic amines, such as piperidine, morpholine and piperazine, and inorganic salts derived  
30 from sodium, calcium, potassium, magnesium, manganese, iron, copper, zinc, aluminum and lithium.

In the case of agents that are solids, it is understood by those skilled in the art that the inventive compounds, agents and salts may exist in different crystal or

polymorphic forms, all of which are intended to be within the scope of the present invention and specified formulas.

A variety of known assays and techniques may be employed to determine the level of activity of various forms of the compounds in the GnRH system. Ligand-binding assays are used to determine interaction with the receptor of interest. Where binding is of interest, a labeled receptor may be used, where the label is a fluorescer, enzyme, radioisotope, or the like, which registers a quantifiable change upon the binding of the receptor. Alternatively, the artisan may provide for an antibody to the receptor, where the antibody is labeled, which may allow for amplification of the signal. Binding may also be determined by competitive displacement of a ligand bound to the receptor, where the ligand is labeled with a detectable label. Where agonist and/or antagonist activity is of interest, an intact organism or cell may be studied, and the change in an organismic or cellular function in response to the binding of the compound of interest may be measured. Various devices are available for detecting cellular response, such as a microphysiometer available from Molecular Devices, Redwood City, California. *In vitro* and *in vivo* assays useful in measuring GnRH antagonist activity are known in the art. See, e.g., Bowers et al., "LH suppression in cultured rat pituitary cells treated with 1 ng of LHRH," *Endocrinology*, 1980, 106:675-683 (*in vitro*), and Corbin et al., "Antiovulatory activity (AOA) in rats," *Endocr. Res. Commun.*, 2:1-23 1975.. Particular test protocols that may be used are described below.

For example, GnRH-receptor antagonists may be functionally assessed by measurement of change in extracellular acidification rates as follows. The ability of compounds to block the extracellular rate of acidification mediated by GnRH in HEK 293 cells expressing human GnRH receptors is determined as a measure of the compound's antagonist activity *in vitro*. Approximately 100,000 cells/chamber are immobilized in agarose suspension medium (Molecular Devices) and perfused with unbuffered MEM media utilizing the Cytosensor® Microphysiometer (Molecular Devices). Cells are allowed to equilibrate until the basal acidification rate remains stable (approximately one hour). Control dose-response curves are performed to GnRH ( $10^{-11}$  M to  $10^{-7}$  M). Compounds are allowed to incubate 15 minutes prior to stimulation with GnRH, and are assessed for antagonist activity. After incubation with test compounds, repeat dose-response curves to GnRH in the presence or absence of various concentrations of the test compounds are obtained. Schild

regression analysis is performed on compounds to determine whether compounds antagonize GnRH-mediated increases in extracellular acidification rates through a competitive interaction with the GnRH receptor.

In another test, accumulation of total inositol phosphates may be measured by 5 formic acid extraction from cells, followed by separation of the phosphates on Dowex columns. Cells are split using trypsin into two 12-well plates and pre-labeled with <sup>3</sup>H-myoinositol (0.5 Ci to 2 mCi per mL) for 16-18 hours in inositol-free medium. The medium is then aspirated and the cells rinsed with either 1X HBSS, 20 mM HEPES (pH 7.5), or serum-free DMEM, 1X HBSS, 20mM HEPES (pH 7.5) 10 containing test compound, and 20 mM LiCl is then added and the cells are incubated for the desired time. The medium is aspirated and the reaction stopped by addition of ice-cold 10 mM formic acid, which also serves to extract cellular lipids. Inositol phosphates are separated by ion-exchange chromatography on Dowex columns, which are then washed with 5 mL of 10 mM myoinositol and 10 mM formic acid. The 15 columns are then washed with 10 mL of 60 mM sodium formate and 5 mM borax, and total inositol phosphates are eluted with 4.5 mL 1M ammonium formate, 0.1M formic acid.

It will be appreciated that the actual dosages of the agents of this invention will vary according to the particular agent being used, the particular composition 20 formulated, the mode of administration, and the particular site, host, and disease being treated. Optimal dosages for a given set of conditions may be ascertained by those skilled in the art using conventional dosage-determination tests in view of the experimental data for a given compound. For oral administration, an exemplary daily dose generally employed will be from about 0.001 to about 1000 mg/kg of body 25 weight, with courses of treatment repeated at appropriate intervals. Administration of prodrugs may be dosed at weight levels that are chemically equivalent to the weight levels of the fully active compounds.

To treat diseases or conditions mediated by GnRH agonism or antagonism, a pharmaceutical composition of the invention is administered in a suitable formulation 30 prepared by combining a therapeutically effective amount (i.e., a GnRH modulating, regulating, or inhibiting amount effective to achieve therapeutic efficacy) of at least one GnRH agent of the invention (as an active ingredient) with one or more pharmaceutically suitable carriers, which may be selected from diluents, excipients and auxiliaries that facilitate processing of the active compounds into the final

pharmaceutical preparations. Optionally, one or more additional active ingredients, such as a second GnRH agent, may be employed in a pharmaceutical composition according to the invention.

The pharmaceutical carriers employed may be either solid or liquid.

5 Exemplary solid carriers are lactose, sucrose, talc, gelatin, agar, pectin, acacia, magnesium stearate, stearic acid and the like. Exemplary liquid carriers are syrup, peanut oil, olive oil, water and the like. Similarly, the inventive compositions may include time-delay or time-release material known in the art, such as glyceryl monostearate or glyceryl distearate alone or with a wax, ethylcellulose,

10 hydroxypropylmethylcellulose, methylmethacrylate or the like. Further additives or excipients may be added to achieve the desired formulation properties. For example, a bioavailability enhancer, such as Labrasol, Gelucire or the like, or formulator, such as CMC (carboxymethylcellulose), PG (propyleneglycol), or PEG (polyethyleneglycol), may be added. Gelucire<sup>®</sup>, a semi-solid vehicle that protects

15 active ingredients from light, moisture and oxidation, may be added, e.g., when preparing a capsule formulation.

If a solid carrier is used, the preparation can be tableted, placed in a hard gelatin capsule in powder or pellet form or in the form of a troche or lozenge. The amount of solid carrier may vary, but generally will be from about 25 mg to about 1 g.

20 If a liquid carrier is used, the preparation may be in the form of syrup, emulsion, soft gelatin capsule, sterile injectable solution or suspension in an ampoule or vial or non-aqueous liquid suspension. If a semi-solid carrier is used, the preparation may be in the form of hard and soft gelatin capsule formulations. The inventive compositions are prepared in unit-dosage form appropriate for the mode of administration, e.g.,

25 parenteral or oral administration.

To obtain a stable water-soluble dose form, a pharmaceutically acceptable salt of an inventive agent may be dissolved in an aqueous solution of an organic or inorganic acid, such as 0.3 M solution of succinic acid or citric acid. If a soluble salt form is not available, the agent may be dissolved in a suitable cosolvent or combinations of cosolvents. Examples of suitable cosolvents include alcohol, propylene glycol, polyethylene glycol 300, polysorbate 80, glycerin and the like in concentrations ranging from 0-60% of the total volume. In an exemplary embodiment, a compound of Formula I, II, or III is dissolved in DMSO and diluted with water. The composition may also be in the form of a solution of a salt form of

the active ingredient in an appropriate aqueous vehicle such as water or isotonic saline or dextrose solution.

Proper formulation is dependent upon the route of administration chosen. For injection, the agents of the invention may be formulated into aqueous solutions, 5 preferably in physiologically compatible buffers such as Hanks solution, Ringer's solution, or physiological saline buffer. For transmucosal administration, penetrants appropriate to the barrier to be permeated are used in the formulation. Such penetrants are generally known in the art.

For oral administration, the compounds can be formulated readily by 10 combining the active compounds with pharmaceutically acceptable carriers known in the art. Such carriers enable the compounds of the invention to be formulated as tablets, pills, dragees, capsules, liquids, gels, syrups, slurries, suspensions and the like, for oral ingestion by a patient to be treated. Pharmaceutical preparations for oral use can be obtained using a solid excipient in admixture with the active ingredient (agent), 15 optionally grinding the resulting mixture, and processing the mixture of granules after adding suitable auxiliaries, if desired, to obtain tablets or dragee cores. Suitable excipients include: fillers such as sugars, including lactose, sucrose, mannitol, or sorbitol; and cellulose preparations, for example, maize starch, wheat starch, rice starch, potato starch, gelatin, gum, methyl cellulose, hydroxypropylmethyl-cellulose, 20 sodium carboxymethylcellulose, or polyvinylpyrrolidone (PVP). If desired, disintegrating agents may be added, such as crosslinked polyvinyl pyrrolidone, agar, or alginic acid or a salt thereof such as sodium alginate.

Dragee cores are provided with suitable coatings. For this purpose, concentrated sugar solutions may be used, which may optionally contain gum arabic; 25 polyvinyl pyrrolidone, Carbopol gel, polyethylene glycol, and/or titanium dioxide, lacquer solutions, and suitable organic solvents or solvent mixtures. Dyestuffs or pigments may be added to the tablets or dragee coatings for identification or to characterize different combinations of active agents.

Pharmaceutical preparations which can be used orally include push-fit 30 capsules made of gelatin, as well as soft, sealed capsules made of gelatin and a plasticizer, such as glycerol or sorbitol. The push-fit capsules can contain the active ingredients in admixture with fillers such as lactose, binders such as starches, and/or lubricants such as talc or magnesium stearate, and, optionally, stabilizers. In soft capsules, the active agents may be dissolved or suspended in suitable liquids, such as

fatty oils, liquid paraffin, or liquid polyethylene glycols. In addition, stabilizers may be added. All formulations for oral administration should be in dosages suitable for such administration. For buccal administration, the compositions may take the form of tablets or lozenges formulated in conventional manner.

5 For administration intranasally or by inhalation, the compounds for use according to the present invention may be conveniently delivered in the form of an aerosol spray presentation from pressurized packs or a nebuliser, with the use of a suitable propellant, e.g., dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafluoroethane, carbon dioxide or other suitable gas. In the case of a  
10 pressurized aerosol the dosage unit may be determined by providing a valve to deliver a metered amount. Capsules and cartridges of gelatin for use in an inhaler or insufflator and the like may be formulated containing a powder mix of the compound and a suitable powder base such as lactose or starch.

15 The compounds may be formulated for parenteral administration by injection, e.g., by bolus injection or continuous infusion. Formulations for injection may be presented in unit-dosage form, e.g., in ampoules or in multi-dose containers, with an added preservative. The compositions may take such forms as suspensions, solutions or emulsions in oily or aqueous vehicles, and may contain formulatory agents such as suspending, stabilizing and/or dispersing agents.

20 Pharmaceutical formulations for parenteral administration include aqueous solutions of the active compounds in water-soluble form. Additionally, suspensions of the active agents may be prepared as appropriate oily injection suspensions. Suitable lipophilic solvents or vehicles include fatty oils such as sesame oil, or synthetic fatty acid esters, such as ethyl oleate or triglycerides, or liposomes.  
25 Aqueous injection suspensions may contain substances which increase the viscosity of the suspension, such as sodium carboxymethyl cellulose, sorbitol, or dextran. Optionally, the suspension may also contain suitable stabilizers or agents which increase the solubility of the compounds to allow for the preparation of highly concentrated solutions.

30 For administration to the eye, a GnRH agent may be delivered in a pharmaceutically acceptable ophthalmic vehicle such that the compound is maintained in contact with the ocular surface for a sufficient time period to allow the compound to penetrate the corneal and internal regions of the eye, including, for example, the anterior chamber, posterior chamber, vitreous body, aqueous humor,

vitreous humor, cornea, iris/ciliary, lens, choroid/retina and selera. The pharmaceutically acceptable ophthalmic vehicle may be an ointment, vegetable oil, or an encapsulating material. A compound of the invention may also be injected directly into the vitreous and aqueous humor.

5 Alternatively, the active ingredient may be in powder form for constitution with a suitable vehicle, e.g., sterile pyrogen-free water, before use. The compounds may also be formulated in rectal compositions such as suppositories or retention enemas, e.g, containing conventional suppository bases such as cocoa butter or other glycerides.

10 In addition to the formulations described above, the compounds may also be formulated as a depot preparation. Such long-acting formulations may be administered by implantation (for example, subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, the compounds may be formulated with suitable polymeric or hydrophobic materials (for example, as an emulsion in an 15 acceptable oil) or ion-exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt.

A pharmaceutical carrier for hydrophobic compounds is a cosolvent system comprising benzyl alcohol, a nonpolar surfactant, a water-miscible organic polymer, and an aqueous phase. The cosolvent system may be a VPD co-solvent system. VPD 20 is a solution of 3% w/v benzyl alcohol, 8% w/v of the nonpolar surfactant polysorbate 80, and 65% w/v polyethylene glycol 300, made up to volume in absolute ethanol. The VPD co-solvent system (VPD: 5W) contains VPD diluted 1:1 with a 5% dextrose in water solution. This co-solvent system dissolves hydrophobic compounds well, and itself produces low toxicity upon systemic administration. The proportions of a 25 co-solvent system may be suitably varied without destroying its solubility and toxicity characteristics. Furthermore, the identity of the co-solvent components may be varied: for example, other low-toxicity nonpolar surfactants may be used instead of polysorbate 80; the fraction size of polyethylene glycol may be varied; other biocompatible polymers may replace polyethylene glycol, e.g. polyvinyl pyrrolidone; 30 and other sugars or polysaccharides may be substituted for dextrose.

Alternatively, other delivery systems for hydrophobic pharmaceutical compounds may be employed. Liposomes and emulsions are known examples of delivery vehicles or carriers for hydrophobic drugs. Certain organic solvents such as dimethylsulfoxide also may be employed, although usually at the cost of greater

toxicity. Additionally, the compounds may be delivered using a sustained-release system, such as semipermeable matrices of solid hydrophobic polymers containing the therapeutic agent. Various sustained-release materials have been established and are known by those skilled in the art. Sustained-release capsules may, depending on 5 their chemical nature, release the compounds for a few weeks up to over 100 days. Depending on the chemical nature and the biological stability of the therapeutic reagent, additional strategies for protein stabilization may be employed.

The pharmaceutical compositions also may comprise suitable solid- or gel-phase carriers or excipients. Examples of such carriers or excipients include calcium 10 carbonate, calcium phosphate, sugars, starches, cellulose derivatives, gelatin, and polymers such as polyethylene glycols.

Some of the compounds of the invention may be provided as salts with pharmaceutically compatible counter ions. Pharmaceutically compatible salts may be formed with many acids, including hydrochloric, sulfuric, acetic, lactic, tartaric, 15 malic, succinic, etc. Salts tend to be more soluble in aqueous or other protonic solvents than are the corresponding free-base forms.

The compounds of Formulas I, II and III and their intermediates may be prepared by advantageous processes described below. Preferred intermediates useful 20 for synthesizing the inventive compounds include 5-(2-methylphenoxy)-2-furoic acid, 5-[2-bromo-5-(tert-butyl)phenoxy]-2-furoic acid, 5-[3,3,6-trimethyl-2,3-dihydro-1H-inden-5-yl)oxy]-2-furoic acid, 5-(4-chloro-5-isopropyl)-2-methylphenoxy)-2-furoic acid, 5-[(4-bromo-3,3,6-trimethyl-2,3-dihydro-1H-inden-5-yl)oxy]-2-furoic acid, and 6-methyl-2-[(3,5,5,8,8-pentamethyl-5,6,7,8-tetrahydro-2-naphthalenyl)oxy]-4-pyrimidinecarboxylic acid. Additional preferred nitro and amine intermediates useful 25 for synthesizing of GnRH agents of the present invention are:

Methods for electrophilic aromatic nitration are described in the art. See, for example, Coon et al., *J. Org. Chem.*, 38: 4243 (1973); Yarbro et al., *J. Fluorine*

*Chem.* 6:187 (1975); Hakimelahi et al., *Hel. Chim. Acta* 61: 906 (1984); Suri et al., *Synthesis* 743(1988); Umenoto et al, *Tetrahedron Lett.* 31:3579 (1990); Shackelford et al., *Abstracts of the 11th Rocky Mountain Regional American Chemical Society Meeting*, Albuquerque, NM, July 10-12, 1992; and Adams et al., *Tetrahedron Lett.* 34: 6669 (1993). These methods have drawbacks, however. For example, the Yarbro et al. and Hakimelahi et al. methods generate anhydrous nitronium triflate using toxic, gaseous nitryl chloride, NO<sub>2</sub>Cl, and corrosive triflic chloride (acid chloride).

Various drawbacks of prior methods have been overcome by the nitration process of the present invention, which comprises forming a nitrating reagent by adding trifluoromethanesulfonic anhydride to 2-tetramethylammonium nitrate in a polar solvent and reacting the nitrating reagent with an aryl or heteroaryl compound.

Advantages of the present method are, e.g.: a) simplified and more rapid aqueous work-up, thereby eliminating chromatographic column separation and/or plug filtration; b) improved reactant solubility and reduced byproduct formation as a result of organic solvents rather than aqueous or easily hydrolyzed, corrosive anhydride solvents; c) facilitated synthesis of regiosomeric nitrated products sometimes not available when using other nitration procedures; d) enables the preparation of novel nitroaromatic and nitroheterocyclic compounds; e) achieves selective and exclusive mono-nitration from mild reaction conditions; f) provides higher product yields than many conventional nitration procedures; g) higher crude nitrated product purity; and h) scaleable over a wide range to provide small or large product quantities.

This nitration method described herein may be used to provide nitrated benzene derivatives (e.g., Compound II) and aromatic heterocyclic intermediates. Such nitrated intermediates are reduced (e.g., Compound II to Compound III) to provide intermediates useful for preparing final GnRH agents of the invention (e.g., Compound V--the compound of Example B52).

General Procedure for the Tetramethylammonium Nitrate-Generated Nitronium Triflate Nitration of Aromatic Compounds (General Procedure):

5

Under nitrogen at room temperature, 2.26–2.39 g trifluoromethanesulfonic anhydride was added dropwise from a pressure-equalized addition funnel to a stirred suspension of 1.12 g tetramethylammonium nitrate (96%) in 20 mL commercial anhydrous (or low water) dichloromethane (DCM) with a slight temperature rise resulting. The addition funnel was rinsed with 8 mL anhyd. DCM, and this rinse was added to the reaction suspension. After stirring for at least 1.5 hours, the stirred suspension was cooled in a dry ice/acetone bath to at least –69°C. The aromatic substrate, 7.50 mmol of in 10 mL DCM, was added dropwise to the stirred nitronium triflate suspension keeping the reaction temperature at –65.0°C or less. The addition funnel was then rinsed with 2 mL anhyd. DCM; this rinse also was added to the stirred reaction suspension. The dry ice/acetone bath could then be removed; however, many reactions proceeded more cleanly if the bath was kept in place 30 to 60 minutes and was then allowed to warm unattended to room temperature over the next 15 to 48 hours. In several reactions, the acetone bath was kept in place one hour and then was replaced with a dry ice/acetonitrile cold bath. The reaction was quenched by adding 15 mL of 5% sodium bicarbonate solution and stirring until bubbling ceased with an aqueous layer pH = 8 (With acidic compounds containing phenolic and carboxylic acid groups, only water was added to maintain an acidic pH).

The reaction contents were transferred with 25 mL DCM and 50 mL H<sub>2</sub>O. The lower DCM layer was separated and washed with 5 x 25 mL H<sub>2</sub>O. The combined H<sub>2</sub>O washes were back-extracted with 25 mL DCM, and the combined DCM portions dried over anhyd. MgSO<sub>4</sub>. DCM removal by rotary evaporation gave crude product. This procedure proportionally can be scaled to larger quantities by directly increasing reactant and solvent amounts while keeping reaction time periods the same.

Compound II, shown below, was obtained in 98% crude yield with an isolated 99% crude product purity from reactant I. Originally synthesized on a 7.5 mmole scale, its synthesis has been scaled up to 2864 mmoles, again, with a resultant 98% crude product yield. One preliminary attempt to synthesize Compound II by the traditional HNO<sub>3</sub>/acetic anhydride solvent procedure was not successful.

**2-chloro-4,6-dimethoxy-5-nitropyrimidine (Compound II):** Reacted 1.31g (7.50mmol) I with 1.50 equivalents of nitronium triflate for 48 hours at room temperature to obtain 1.61g II, (98%). FW = 219.6; <sup>1</sup>H NMR (DMSO-d<sub>6</sub>) δ 4.06 (s, 6H); GC/MS (CI, *m/z*) 220 (M<sup>+</sup> and base peak); FTIR (KBr) 3126, 3073, (aromatic CH); 3000, 2958, 2924, 2852 (aliphatic CH); 1524, 1354, (NO<sub>2</sub>), cm<sup>-1</sup>; mp uncorrected = 131.8 to 132.0 °C; Elem. Anal. for C<sub>6</sub>H<sub>6</sub>ClN<sub>3</sub>O<sub>4</sub> (crude product) calculated C 32.82%, H 2.75%, N 19.14%, Cl 16.15, found C 33.12 %, H 2.81%, N 18.95%, Cl 16.43.

**2-chloro-4,6-trimethoxypyrimidin-5-amine (Compound III):** A 500 mL three-necked, round bottom flask containing a Teflon-coated magnetic stirring bar and a thermometer was charged with 10.00 g (45.54 mmol) 2-chloro-4,6-dimethoxy-5-nitropyrimidine, 100 mL 190 proof ethanol, and 50 mL saturated, aqueous ammonium chloride solution. The resultant suspension was stirred at room temperature for several minutes while iron powder (-325 mesh) was added in several portions over a 22 minute period such that the reaction temperature from a slow rising exotherm did not exceed 56 °C. After addition of all the iron powder, the reaction was stirred for two and one-half hours in a room temperature environment. The reaction suspension was suction filtered, and the isolated iron powder was washed with 2 x 25 mL of

ethanol, followed by 3 x 25 mL of ethyl acetate. To the organic filtrate was added 200 mL water and 50 mL more ethyl acetate to effect separation. The upper organic layer was separated, and the lower aqueous layer was extracted with 3 x 50 mL of ethyl acetate. All ethyl acetate portions were combined and dried over anhydrous magnesium sulfate. Suction filtration, washing the spent magnesium sulfate with 15 mL ethyl acetate, and rotary evaporation left a pinkish, wet solid. The wet solid was dissolved in 75 mL dichloromethane, and the dichloromethane was washed with 3 x 25 mL of water. The combined water washings were back-extracted with 25 mL dichloromethane. The combined dichloromethane portions were dried over anhydrous magnesium sulfate. Suction filtration, washing the spent magnesium sulfate with 25 mL dichloromethane, and rotary evaporation afforded 8.21 g (95%) of a cream-colored solid shown to be 98% pure by HPLC analysis. The NMR and mass spectrometry data consistent with the desired product is as follows: FW = 189.6; <sup>1</sup>H NMR (DMSO-d<sub>6</sub>) δ 4.59 (s, 2H), 3.89 (s, 6H); FI/MS (APCI, m/z) 192.0, 190.0 (M<sup>+</sup>+1); FTIR (ATR film) 3420, 3342, 3290 (NH) 3180, 3010, (aromatic CH); 2960, 2871 (aliphatic CH); 1587, 1488, 1458, 1398, 1375, 1314, 1197, 1067, 942 (fingerprint) cm<sup>-1</sup>; Elem. Anal. for C<sub>6</sub>H<sub>8</sub>ClN<sub>3</sub>O<sub>2</sub> calculated: C 38.01%, H 4.25%, Cl 18.70, N 22.16%, found C 38.24 %, H 4.32%, Cl 18.70, N 22.09%.

The synthesis of VII was also achieved by direct nitronium triflate nitration of VI in a 73% crude yield with 85% crude yield purity. This represents the first synthesis of VII by direct nitration. Use of the acetic anhydride/nitric acid nitration procedure gave several byproducts plus VII in only 16% purity. The only other literature preparation appearing in the Beilstein electronic data base for VII produced it from VI and gave a 66% yield [Cherkasov, V. M.; Remennikov, G. Ya.; Kisilenko, A. A. *Chem. Heterocycl. Compd.* (Engl. Transl.); EN; 526 (1982)].

**2,4,6-trimethoxy-5-nitropyrimidine (Compound VII):** Into a 5-L three-necked, round bottom flask fitted with an overhead mechanical stirrer, was placed 920 g (0.675 mole) of tetramethylammonium nitrate and 1 L DCM. The reaction flask was fitted with a thermometer and addition funnel. The suspension was stirred under

nitrogen gas for 15 minutes at room temperature. Into the addition funnel was placed 190 g (0.675 mole, 118mL) of trifluoromethanesulfonic anhydride that was added dropwise to the stirred suspension over a 35 minute duration so the temperature did not rise more than 5 °C. The addition funnel was rinsed with a small amount of DCM, 5 and this rinse was added to the stirred reaction suspension. The resultant suspension was stirred at room temperature for 1.5 hours. The addition funnel was charged with 76.9 g (0.452 mole) dissolved in a minimum amount of DCM and was added dropwise at room temperature over 85 minutes such that the reaction temperature did not rise more than 5 °C, and a bright crimson red suspension resulted. The reaction 10 was stirred overnight at room temperature. Work up entailed adding 5 kg of ice to the stirred reaction suspension followed by 10% NaHCO<sub>3</sub> solution until a pH 8 was reached and the reaction turned from a burgundy to purple to blue to green to yellow color change. The lower DCM layer was separated and washed with 3 x 1.5 L of water. The DCM portion was then dried sodium sulfate, filtered, and the DCM 15 solvent was removed by rotary evaporation giving *ca.* 70 g of green solid. Recrystallization from methanol/water in two crops afforded 50.5 g of purified product for an overall 52% yield. The NMR and mass spectrometry data consistent with the desired product is as follows: FW = 215.2; <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 4.06 (s, 6H), 4.02 (s, 3H); FI/MS (APCI, *m/z*) 216 (M<sup>+</sup>+1 and base peak); FTIR (ATR film) 3047, 2009, 2999 (aromatic CH); 2957, 2877, 2847 (aliphatic CH); 1578, 1338 (NO<sub>2</sub>), cm<sup>-1</sup>; 20 Ele. Anal. for C<sub>7</sub>H<sub>9</sub>N<sub>3</sub>O<sub>5</sub> calculated: C 39.07%, H 4.22%, N 19.53%, found C 39.14 %, H 4.19%, N 19.61%.

### VIII

Compound VIII represents another class of aromatic heterocycle product 25 that was obtained by the above mentioned nitronium triflate method and demonstrates that a pendant ester group also is not attacked nor modified by these nitration conditions.

Anhydrous, Electrophilic, Aromatic Nitration with Tetramethylammonium Nitrate:

Nitration of non-heterocyclic aromatic compounds are also achieved with this anhydrous, one-pot, two-step method in which the nitronium triflate XVI nitrating reagent is generated *in-situ* under a static nitrogen gas blanket from

- 5 tetramethylammonium nitrate XIV and trifluoromethanesulfonic anhydride (triflic anhydride) XV. The aromatic compound to be nitrated is then introduced XVII. Nitration occurs to produce the desired product XVIII plus the tetramethylammonium triflate salt byproduct XIX.

- 10 When using the tetramethylammonium nitrate reagent XIV, the resulting salt byproduct XIX is water soluble and is removed during an aqueous work-up leaving only the desired nitrated product XVIII after drying. Under similar reaction conditions, higher homologues of XIV (*e.g.* tetra-*n*-butylammonium nitrate and tetraethylammonium nitrate) require additional, time intensive purification by column chromatography or short column Silica Gel filtration to remove the analogous XIX byproduct. The one lower homolog, ammonium nitrate, gives irreproducible results under analogous nitration conditions.

20 Most reactions have been conducted in methylene chloride solvent at room temperature. However, chloroform, dichloroethane, and nitromethane also would be suitable solvents and would permit higher temperatures to be achieved by refluxing the reaction in step 2 with electron-deficient aromatic ring systems or when attempting to effect aromatic dinitration.

From 1.05 to 1.50 equivalents of nitronium triflate have been used for mononitration of the aromatic or heterocyclic reactant with excess reagent having no deleterious effect. The less reactive the reactant, the larger the excess of nitronium

triflate is needed for complete conversion. More than 1.5 equivalents of nitronium triflate could be used; no upper limit has been determined.

This reaction method (General Procedure) has been scaled linearly from the 7.5 mmole size (aromatic compound to be nitrated) to 92.9 mmoles. To date, no 5 upper limit has been established. It appears this method is limited only by the size of equipment available.

#### Additional Nitration Examples:

The following mono-substituted benzene compounds were evaluated for directing effects and substituent stability during the reaction conditions of this 10 nitration method (ND = not detected). Table 1 illustrates the wide scope of mono-substituted benzenes nitrated with this method and reveals the directional susceptibility of nitronium triflate nitration to aromatic pendant group effects. The nitrations were conducted with 1.05 equivalents of nitronium triflate as described by the General Procedure. Reaction conditions were not optimized for 15 these exploratory reactions, and isomeric percentages were determined by proton NMR analysis of the isolated crude products.

This one-pot tetramethylammonium nitrate-based nitration also was applied to multiple-substituted aromatic compounds under the same reaction conditions. Table 2 displays the results obtained.

B.  $\text{NO}_2\text{OTf}$  equivalents = 1.50 relative to the reactant 14.

10      Compound purity was determined by HPLC analysis. Crude product 9 was purified further by preparative HPLC to greater than 99%. Compound 13 was purified by recrystallization from hexane. Both 9 and 13 gave acceptable elemental analyses. The only previous synthesis of 13 by direct nitration used fuming nitric acid at 5 °C for one hour, and gave a 70% crude product yield with an apparent purification obtained from an ethanol recrystallization as described by Garg et al., *J. Chem. Soc.*, 607, (1969). Compound 10 and its products 11a and 11b reveal that the sterically crowded position between 1,3-disubstituted methoxy groups is not attacked when less sterically hindered positions are available. When no alternative is available, nitration readily occurs between two 1,3-di-substituted methoxy groups as shown by 2,4,6-trimethoxybenzonitrile 14 where product 15 is obtained in good yield and purity. Other than the equivalents of  $\text{NO}_2\text{OTf}$ , used, the main difference in reaction conditions between the latter two runs of reactant 14 was reactant 14 had a slower warming profile that gave the highest crude yield and purity for product 15. In the first two reactions with 14, the dry ice/acetone

cooling bath was removed immediately after adding reactant **14** like that described in the General Procedure. The better result in the third reaction of **14** was obtained by replacing the dry ice/acetone cooling bath with a dry ice/acetonitrile cooling bath for 2.5 hours (-50°C to -35°C), allowing the bath to warm to 9°C over 5 the next 2.5 hours, then removing the cooling bath completely and stirring the reaction for 48 hours. Product **15** has not previously been reported in the chemical literature and represents a new compound.

This General Procedure scales directly from 7.5 to 100 millimoles by proportionally increasing the amounts of reagent and solvent while keeping 10 reaction times the same. Results of large-scale reactions appear in Table 3. Unless stated otherwise, product particles were determined by HPLC analysis.

As shown in Tables 2 and 3, the brominated acetyl group of reactant **12** was stable to the mild nitronium triflate electrophilic nitration conditions. The carbonyl group in aldehyde, and carboxylic acid groups are compatible with this nitration procedure (Table 1), as is an ester group, and the unsaturated cyano group is compatible with this reaction.

In the smaller 7.5 milligram scale nitration of reactant **10**, nine percent of product isomer **11b** was obtained and was removed by recrystallization. No formation of product **11b** was obtained in the larger scale reaction, see Table 3. Compound **23** selectively produced the one isomeric product **24a** in an excellent yield. In contrast, a literature nitration of **23** using the nitronium tetrafluoroborate reagent ( $\text{NO}_2^+ \text{BF}_4^-$ ) produced 5% **24b** by product as an impurity as described in Olah et al, *J. Am. Chem. Soc.*, 86, 1067, (1964).

Compound **29** nitrated by this method gave different results when compared with the standard acetic anhydride/nitric acid nitration system. Each method gave the different regioisomer in exclusive or a nearly exclusive yield. The nitronium triflate method heavily favored *ortho*-nitration with respect to the methylsulfamide group **30a**, while the standard acetic anhydride/nitric acid method provided exclusive *para*-nitration **30b**.

In the oxidative environment of this *in-situ* nitration method, aromatic alkylsulfides **31** are cleanly oxidized to their analogous sulfoxide **32**, and the sulfoxide **32** is then oxidized to a sulfone **33** in an apparent stepwise fashion. Once the fully oxidized sulfone **33** is obtained, nitration can then occur to provide the mono-nitrated sulfone **34**. This is illustrated by the three following non-optimized reactions.

In each reaction step, only the product and unconverted reactant were detected with no byproducts present. With the correct number of nitronium triflate equivalents, unique aromatic sulfones could be made during a clean, one-pot reaction.

The nitrated products obtained by this nitration method shown in Tables 2 and 3 were characterized as follows:

**Procedural Notes:**

15 Reactant **14** (Table 2): the first two runs were conducted by removing the dry ice/acetone bath as described in the General Procedure. The best small-scale result with **14** used a slower warming profile by replacing the dry ice/acetone cooling bath with a dry ice/acetonitrile cold bath fro 2.5 hours (-49.6°C to -35.0°C), allowing the bath to warm to 9.0°C over the next 2.5 hours (-35.0°C-9.0°C), then removing the bath  
20 completely and stirring for 48 hours. This led to the following temperature warming modification for the large-scale nitrations with reactants **14**, **25**, and **27**. After addition of aromatic reactant, the reaction was kept one hour in the dry ice/acetone bath; then, it was then replaced with a dry ice/acetonitrile bath (*ca.* -45°C) for three hours, after which, the bath was permitted gradually to warm unattended to room  
25 temperature (RT) over the nexr 48 hours. For compound **23**, the dry ice/acetone bath was removed as soon as addition was complete and was stirred in a RT environment for 24 hours. For compound **12** (large scale), the dry ice/acetone bath was not removed following its addition, but was left in place to warm gradually, unattended to RT over the next 23 hours.

**Synthesis Of GnRH Reagents And Compounds:**

The inventive agents may be prepared using the reaction routes and synthesis schemes as described below, employing the techniques available in the art using starting materials that are readily available. The preparation of preferred compounds  
35 of the present invention is described in detail in the following examples, but the artisan will recognize that the chemical reactions described may be readily adapted to prepare a number of other protein kinase inhibitors of the invention. For example, the synthesis of non-exemplified compounds according to the invention may be

successfully performed by modifications apparent to those skilled in the art, e.g., by appropriately protecting interfering groups, by changing to other suitable reagents known in the art, or by making routine modifications of reaction conditions. Alternatively, other reactions disclosed herein or known in the art will be recognized  
5 as having applicability for preparing other compounds of the invention.

Reagents useful for synthesizing compounds may be obtained or prepared according to techniques known in the art. For example, the preparation of free amines from common salt forms and stock reagent solutions can be useful for small-scale reactions. See also Abdel-Magid *et al.*, "Reductive Amination of Aldehydes and  
10 Ketones with Sodium Triacetoxyborohydride," *J. Org. Chem.* 61: 3849 (1996).

Methanolic solutions of the free bases can be prepared from hydrochloride, dihydrochloride, hydrobromide, or other salts when the free base is soluble in methanol. In this procedure, once the sodium methoxide is added, care should be taken to prevent exposure to air, since amine free bases, particularly primary amines,  
15 absorb carbon dioxide from the air to form salts. A 10-mL quantity of a 0.1M solution of a free base in methanol may be prepared as follows. Weigh 1.0 mmol of a monohydrochloride salt into a tared Erlenmeyer flask containing a stirring bar, and add 7 mL of methanol. To the stirred slurry, add 229 mL (1.0 mmol, 1 equiv.) of sodium methoxide in methanol (25 wt %, 4.37 M), stopper the flask, and stir the mixture vigorously for 2 hours. The slurry will sometimes change in appearance as a finer, milky precipitate of sodium chloride is formed. Filter the slurry through a 15-mL medium fritted glass funnel, wash the filter case with 1-2 mL methanol, transfer the filtrate to a 20-mL vial, and dilute to 10 mL with methanol. The theoretical yield  
20 of sodium chloride is nearly 59 mg, but the recovery is usually not quantitative, owing to a slight solubility in methanol. For a dihydrochloride salt, a second equivalent of sodium methoxide is required (458 mL).

A 0.5 M solution of sodium borohydride in ethanol may be prepared as follows. Sodium borohydride (520 mg, 13.8 mmol) is stirred in pure (non-denatured) anhydrous ethanol (25 mL) for ~2-3 minutes. The suspension is filtered through a  
30 medium fritted glass funnel to remove a small amount of undissolved solid (typically about 5% of the total mass of borohydride, or 25 mg). The filtrate should appear as a colorless solution that evolves only a little hydrogen. This solution should be used immediately, as it decomposes significantly over a period of a few hours, resulting in the formation of a gelatinous precipitate. Sodium borohydride is hygroscopic, so

5 avoid exposure to air by making the solution at once after weighing the solid. Sodium borohydride has a solubility of about 4% in ethanol at room temperature. This corresponds to a little over 0.8 M. However, sometimes a small percentage of the solid remains undissolved regardless of the concentration being prepared, even after stirring for  $\geq$  5 minutes.

Material and Methods:

In the examples described below, unless otherwise indicated, all temperatures in the following description are in degrees Celsius and all parts and percentages are by weight, unless indicated otherwise.

10 Various starting materials and other reagents were purchased from commercial suppliers, such as Aldrich Chemical Company or Lancaster Synthesis Ltd., and used without further purification, unless otherwise indicated. Tetrahydrofuran (THF) and N,N-dimethylformamide (DMF) were purchased from Aldrich in SureSeal® bottles and used as received. All solvents were purified by using standard methods in the art,  
15 unless otherwise indicated.

The reactions set forth below were performed under a positive pressure of nitrogen or with a drying tube, at ambient temperature (unless otherwise stated), in anhydrous solvents, and the reaction flasks are fitted with rubber septa for the introduction of substrates and reagents via syringe. Glassware was oven-dried and/or

Exemplary GnRH Agents:

The following compounds were prepared according to Scheme A set forth below:

25 Scheme A

**Potassium phenoxide 10:** A mixture of potassium hydroxide (2.55g, 44.8 mmol) and the appropriate phenol 9 (52.9 mmol) was heated in an oil bath at 150-155 °C for 1-2 hours. The dark colored liquid was then evacuated at 130-140 °C to remove water. The residue (potassium phenoxide 10) was dried *in vacuo* overnight. Alternatively, the phenoxide 10 may be prepared by reaction with potassium t-butoxide in tetrahydrofuran.

**Condensation 12:** A mixture of potassium phenoxide 10 (7 mmol), prepared as described above, and methyl 5-bromo-2-furoate 11 (5.8 mmol) in DMSO (10 mL) was heated at 85 °C under nitrogen atmosphere. The reaction mixture was then diluted with water, and the aqueous mixture was acidified with concentrated HCl, and then extracted with diethyl ether. The combined ether extracts were concentrated and the product 12 was purified by silica gel chromatography, eluting with a mixture of ethyl acetate and hexanes (1:5 to 1:1 v/v). Yield was in the range of 50-80%.

**Saponification 13:** The methyl ester 12 obtained from above was dissolved in methanol (4 mmol in 15 mL of solvent). An aqueous solution of sodium hydroxide (0.7g in 5 mL water) was added. The mixture was monitored by TLC for completion of reaction. It was concentrated, diluted with water, and extracted with diethyl ether. The aqueous layer was then acidified with concentrated HCl, and extracted with ethyl acetate. The ethyl acetate extracts were washed with brine, dried over magnesium sulfate and concentrated to give a solid residue. The product 5-substituted-2-furoic acid 13 may be purified, if necessary, by silica gel chromatography. Yield was greater than 90%.

**Amide Formation:** Procedure 1: The furoic acid 13 from above (1 mmol) was dissolved in dimethylformamide (5 mL). To this solution was added 1-ethyl-3-(3-

dimethylaminopropyl) carbodiimide hydrochloride (EDCI, 1 mmol), followed by the addition of the appropriate aniline or aniline hydrochloride (1 mmol), and triethylamine (1.1 mmol). The reaction mixture was stirred at room temperature overnight. DMF was removed on a rotovap. The residue was suspended in ethyl acetate, and washed with 10% HCl (aqueous), aqueous sodium bicarbonate, brine, and dried over magnesium sulfate. The solvent was removed on a rotovap. The product 15 was purified by silica gel chromatography using a mixture of ethyl acetate/hexanes (2/1 v/v) as the eluting solvent.

Procedure 2: The furoic acid 13 from above (1 mmol) was dissolved in dimethylformamide (5 mL). To this solution was added HATU (1 mmol), followed by the addition of the appropriate aniline or aniline hydrochloride (1 mmol), and triethylamine (2-3 mmol). The reaction mixture was stirred at room temperature overnight. DMF was removed on a rotovap. The residue was suspended in ethyl acetate, and washed with 10% HCl (aqueous), aqueous sodium bicarbonate, brine, and dried over magnesium sulfate. The solvent was removed on a rotovap. The product 15 was purified by silica gel chromatography using a mixture of ethyl acetate/hexanes (2/1 v/v) as the eluting solvent.

This procedure may be applied to the synthesis of anilides of the present invention. Alternatively, the appropriate amide 15 may be prepared via carboxylic acid chloride 14. A suspension of 13 (300mmol) in anhydrous benzene (100ml) containing a few drops of anhydrous DMF was heated to reflux under nitrogen as thionyl chloride(1.1 eq.) in benzene (35ml) was added dropwise. The solution was refluxed for 10 hours and then cooled to room temperature and concentrated under vacuum to give 14. A mixture of the appropriate aniline or aniline hydrochloride salt (1.2eq.) and triethylamine (2.5eq) in dichloromethane was stirred at 0°C under nitrogen as a solution of 14 in dichloromethane was added dropwise. The solution was allowed to warm to room temperature and further stirred for 12 hours. The resulting suspension was washed several times with 2N hydrochloric acid, saturated sodium bicarbonate, brine and water successively. The organic layer was dried over anhydrous sodium sulfate, concentrated under vacuum to give 15 which was then purified by column chromatography.

**Assessment of GnRH Receptor Activation Using Microphysiometry**

10 By performing exemplary assays described below, the functionality of the compounds of the invention as GnRH antagonists may be confirmed.

**Materials and Methods.**

GnRH, Ac-D-2-Nal-p-chloro-D-Phe- $\beta$ -(3-pyridyl)-D-Ala-Ser-Lys(nicotinoyl)-D-Lys(nicotinoyl)-Leu-Lys(isopropyl)-Pro-D-Ala-NH<sub>2</sub> (antide), the superagonist peptide [D-Ala<sup>6</sup>, des-Gly<sup>10</sup>]proethylamide<sup>9</sup>-LHRH (GnRH-A), and TRH may be purchased from Bachem (Torrance, CA). 25 **Cell Culture.** GGH<sub>3</sub> cells (Dr. William Chin, Harvard Medical School, Boston, MA) are grown in low glucose Dulbecco's modified Eagle's medium (DMEM) containing 100U/mL penicillin/streptomycin, 0.6 g/L G418 and 10% heat-inactivated FBS.

**Total Inositol Phosphates Measurement.**

The activity of various GnRH peptide agonists is initially assessed utilizing an 30 assay that measures accumulation of total inositol phosphates. Approximately 200,000 GGH<sub>3</sub> cells/well are plated onto 24-well tissue culture plates using DMEM media. The following day, cells are loaded with [<sup>3</sup>H]myoinositol (0.5 Ci/ml) for 16-18

hours in inositol-free medium. The medium is aspirated and the cells rinsed with serum-free DMEM. Cells are stimulated with GnRH (0.1 nM—1  $\mu$ M) or the superagonist, GnRH-A (0.01 nM—100 nM) dissolved in DMEM media in a total volume of 1 mL containing 10 mM LiCl at 37°C for 45 minutes. The media is replaced with 1 mL ice-cold 10 mM formic acid, which stops the reaction and also serves to extract cellular lipids. Inositol phosphates are separated by ion-exchange chromatography on Dowex columns, which are washed with 2.5 mL of 10 mM myoinositol and 10 mM formic acid. The columns are then washed with 5 mL of 60 mM sodium formate and 5 mM borax, and total inositol phosphates are eluted with 5 mL 1M ammonium formate, 0.1 M formic acid. The column eluates are added to liquid scintillation vials containing 15 ml of scintillation cocktail and are counted by liquid scintillation counting.

Preparation of  $^{125}$ I-GnRH-A radioligand.

The radioiodinated agonist analog of GnRH,  $^{125}$ I-GnRH-A, is used as the radioligand. One  $\mu$ g of GnRH-A diluted in 0.1M acetic acid is added to an Iodogen®-coated borosilicate glass tube (Pierce) containing 35  $\mu$ l of 0.05 M phosphate buffer (pH 7.4-7.6) and 1 mCi of Na[ $^{125}$ I]. The reaction mixture is vortexed and incubated for 1 min at room temperature. 2 ml of 0.5 M acetic acid is added to the reaction tube and the mixture is added to a C18 Sep-Pak cartridge. The cartridge is washed with subsequent washes of 5 ml H<sub>2</sub>O and 5 ml 0.5M acetic acid and then eluted with 5 x 1 ml of 60% CH<sub>3</sub>CN/40% 0.5M acetic acid. The eluate is diluted with 3x volume of HPLC buffer A (0.1% TFA in H<sub>2</sub>O) and loaded onto a C18 column. The iodinated product is eluted over 20-25 min with a gradient of 25-100% CH<sub>3</sub>CN containing 0.1%TFA. The radioactive fractions (750  $\mu$ l/fraction) are collected into clean polypropylene tubes containing 100  $\mu$ l of 10% BSA. Fractions are assessed for biological activity by radioligand binding.

Competition Radioligand Binding.

Approximately two million GGH<sub>3</sub> cells/tube are utilized for radioligand binding.  $^{125}$ I-GnRH-A (approximately 0.1-0.3 nM) is incubated with cells in the presence or absence of competing agents in a final volume of 300  $\mu$ l binding assay buffer [50 mM HEPES (pH 7.4), 1 mM EDTA, 2.5 mM MgCl<sub>2</sub>, and 0.1% BSA] to test the ability of compounds to displace agonist binding. Reactions are performed on ice for 2 hr and stopped by the addition of 2 ml of ice-cold PBS wash buffer (50 mM

NaPO<sub>4</sub>, 0.9% NaCl, 2 mM MgCl<sub>2</sub>, and 0.02% NaN<sub>3</sub>, pH 7.4) and rapid filtration onto GF/C filters presoaked with 0.05% polyethylenimine utilizing a Brandel cell harvester. Filters are counted on a gamma counter.

Microphysiometry.

The Cytosensor® Microphysiometer (Molecular Devices, Sunnyvale, CA) is a real-time, noninvasive, nonradioactive semiconductor-based system for monitoring the cellular responses to various stimuli. It is based on a pH-sensitive silicon sensor, the light-addressable potentiometric sensor which forms part of a microvolume flow chamber in which cultured cells are immobilized (14, 15, 17). GGH<sub>3</sub> cells are seeded in low-buffered minimal essential media (MEM, Sigma) containing 25 mM NaCl and 0.1% BSA at a density of 500,000 cells/capsule onto the polycarbonate membrane (3 µm porosity) of cell capsule cups (Molecular Devices, Sunnyvale, CA). Capsule cups are transferred to sensor chambers where cells are held in close apposition to a silicon sensor within a sensor chamber, which measures small changes in pH in the microvolume of the sensor chamber. Low-buffered medium is pumped continuously across the cells at a rate of approximately 100 µl/min from one of two fluid reservoirs. A selection valve determines which reservoir from which fluid is perfused onto the cells.

The Cytosensor® Microphysiometer generates a voltage signal, which is a linear function of pH, every second. In order to measure acidification rates, flow to the sensor chamber containing the cells is periodically interrupted, allowing excreted acidic metabolites to build up in the extracellular fluid of the cells. Cells are maintained at 37 °C on a two-minute flow cycle with cells being perfused with media for 80 seconds followed by 40 seconds in which the flow of media is stopped. During this 40-second interval, acidification rates are measured for a 30 sec interval. In this fashion, a single acidification rate is calculated every two min. The Cytosensor® Microphysiometer device contains eight such sensor units, allowing for eight simultaneous experiments to be performed. Each unit is individually programmed utilizing a computer linked to the system.

GGH<sub>3</sub> cells are initially equilibrated in the low-buffered MEM media for a period of 30-60 min in which basal acidification rates (measured as µV/sec), in the absence of any stimuli, are monitored. When the basal rate of acidification changes by less than ten percent over a period of twenty minutes, experiments are initiated.

Time course experiments are performed to determine the optimal time for agonist exposure prior to acidification rate measurement and the duration of exposure needed to obtain peak acidification responses to various agonists. From these time course experiments, it has been determined that cells should be exposed to GnRH peptide agonists at least one minute prior to collection of acidification rate data. Peak acidification rates usually occur in the first two-min exposure cycle. When the effects of various inhibitors are measured, cells are pretreated for 20 min with test compound diluted in low-buffered MEM containing 1% DMSO final concentration prior to exposure of the cells for 4 min to a solution containing GnRH or PMA at appropriate concentration in the presence of inhibitor.

Cyclic AMP Measurement.

The ability of various compounds to increase basal cAMP formation in GGH<sub>3</sub> cells is assessed utilizing 96-well adenylyl cyclase flashplates purchased from New England Nuclear (NEN, Boston, MA). Cells (approximately 50,000 cells/well) are incubated with either forskolin (10 nM—10 µM), GnRH (1 nM—1 µM) or GnRH-A (0.1 nM—100 nM) in a total volume of 100 µl on flashplates for 20 minutes at room temperature to assess for agonist activity. 100 µl of detection mix containing <sup>125</sup>I-cAMP is added to quench reactions according to the manufacturer's instructions. Plates are counted on a Packard TopCount after approximately two hours. Cyclic AMP levels are determined from standard curves generated to non-radioactive cAMP standards (10 nM-1 µM).

Data Analysis.

Cytosensor® Microphysiometer data are normalized utilizing Cytosoft® software (Molecular Devices, Sunnyvale, CA). EC<sub>50</sub> values for agonists and IC<sub>50</sub> values for inhibitors are generated utilizing Prism™ (version 2.01, GraphPad Software, San Diego, CA), a computer graphics and statistics program. Values for multiple experiments are presented as means ± SE of at least three replicate experiments.

Effect of Compounds on <sup>125</sup>I-GnRH-A Binding to GGH<sub>3</sub> Cells.

In order to assess the specific functionality, compounds were assessed for their ability to inhibit <sup>125</sup>I-GnRH-A binding to GGH<sub>3</sub> cells. The peptide ligands GnRH, GnRH-A, and Antide, but none of the tested compounds of the invention, blocked

<sup>125</sup>I-GnRH-A binding to these cells. Thus, the compounds of the invention are GnRH antagonists.

Determination of Binding Inhibition Constants

Using the assay described below, K<sub>i</sub> values for compounds of the invention  
5 were determined.

Chemicals and Reagents.

GnRH (pGlu-His-Trp-Ser-Tyr-Gly-Leu-Arg-Pro-Gly-NH<sub>2</sub>), was purchased  
from Bachem (Torrance, CA). Cell Culture media was purchased from Sigma (St.  
Louis, MO). Fetal bovine serum (FBS) was from Omega Scientific, Inc. (Tarzana,  
10 CA). G418 and penicillin/streptomycin were from Gemini (Calabasas, CA).  
Newborn calf serum was from Summit Biotech (Fort Collins, CO). All other reagents  
were of the highest quality from standard sources.

Cell Culture.

HEK 293 cells stably transfected with mouse or human GnRH receptors as  
15 described above were grown in Dulbecco's high-glucose, modified Eagle's medium  
(DMEM) supplemented with 0.2% G418, 10% fetal bovine serum (FBS) and  
100U/mL penicillin/streptomycin. GH<sub>3</sub> cells stably transfected with the rat GnRH  
receptor (GGH<sub>3</sub>) were provided by Dr. William Chin (Harvard Medical School,  
Boston, MA). These cells have been extensively characterized previously (Kaiser et  
20 al., 1997). The cells were grown in low glucose DMEM containing: 100U/mL  
penicillin/streptomycin, 0.6% G418 and 10% heat-inactivated FBS.

Cell Membrane Preparation.

HEK 293 cells containing mouse or human receptors, or rat pituitaries (Pel  
Freez Biologicals, Rogers, AR) were homogenized in buffer A containing: 50 mM  
25 Tris (pH 7.4), 0.32 M sucrose, 2 mM EGTA, 1 mM PMSF, 5 µg/ml aprotinin, 5  
µg/ml Pepstatin A, and 1 µg/ml leupeptin. Homogenized cells were centrifuged at  
4°C at 20,000 x g for 25 minutes, re-suspended in buffer A and re-centrifuged at 4°C  
at 20,000 x g for an additional 25 minutes. Total membrane protein was determined  
30 with a BCA kit (Pierce, Rockford, IL). Membranes were stored at -70°C at a final  
membrane protein concentration of approximately 5 mg/ml.

Radioligand Preparation.

The radioiodinated agonist analog of GnRH, [des-Gly<sup>10</sup>,D-Ala<sup>6</sup>]GnRH  
ethylamide (<sup>125</sup>I-GnRH-A), was used as the radioligand. One µg of GnRH-A diluted

in 0.5 M phosphate buffer (pH 7.4) was added to an Iodogen®-coated borosilicate glass tube (Pierce, Rockford, IL) containing 35 µl of 0.05 M phosphate buffer (pH 7.4-7.6) and 1 mCi of Na[<sup>125</sup>I]. The reaction mixture was vortexed and incubated for 1 minute at room temperature. After one minute, the mixture was vortexed and  
5 allowed to incubate for an additional minute. 2 ml of 0.5 M acetic acid/1% BSA was added to the reaction tube and the mixture was added to a C18 Sep-Pak cartridge. The cartridge was washed with subsequent washes of 5 ml H<sub>2</sub>O and 5 ml 0.5 M acetic acid and then eluted with 5 x 1 ml of 60%CH<sub>3</sub>CN/40% 0.5 M acetic acid. The eluate was diluted with 3x volume of HPLC buffer A (0.1% TFA in H<sub>2</sub>O) and loaded onto a  
10 C18 column. The iodinated product was eluted over 20-25 min with a gradient of 25-100% CH<sub>3</sub>CN containing 0.1% TFA. The radioactive fractions (750 µl/fraction) were collected into clean polypropylene tubes containing 100 µl of 10% BSA. Fractions were assessed for biological activity by radioligand binding. Specific activity of the radioligand was approximately 2200 Ci/mmol.

15 Radioligand Binding Assays.

Membranes were diluted to 0.01-0.5 mg/ml (depending upon the species of receptor) with assay buffer containing 50 mM HEPES (pH 7.4), 1 mM EDTA, 2.5 mM MgCl<sub>2</sub>, and 0.1% BSA. Membranes (diluted to utilize similar receptor numbers between assays) were incubated with approximately 0.04-0.06 nM <sup>125</sup>I-GnRH-A in  
20 the presence or absence of competing agents (0.1 – 10,000 nM) in a total volume of 200 µl in 96-well polypropylene plates for 1 hour at room temperature. Assays were stopped by rapid filtration onto 96-well GF/C filters soaked in 0.1% polyethylenimine (PEI) utilizing a Packard 96-well cell harvester. Filters were washed three times with ice-cold PBS (50 mM NaPO<sub>4</sub>, 0.9% NaCl, 2 mM MgCl<sub>2</sub>, and 0.02% NaN<sub>3</sub>, pH 7.4).  
25 35 µl of scintillation cocktail was added to each filter well and filters were counted on a Packard Topcount. Control dose-response curves were generated to GnRH (0.1 nM-100 nM) in each competition binding experiment. Binding inhibition constants (K<sub>i</sub>) for the GnRH agents were calculated and are provided in Table 2 below. K<sub>i</sub> values were calculated from IC50 values according to Cheng et al., *Biochemical Pharmacol.*  
30 22: 3099-3108, 1973.

$$K_i = \frac{\frac{IC_{50}}{1 + [ligand]}}{K_d \text{ of ligand}}$$

#### Microphysiometry.

GGH<sub>3</sub> cells were seeded in low-buffered minimal essential media (MEM, Sigma) containing 25 mM NaCl and 0.1% BSA at a density of 500,000 cells/capsule onto the polycarbonate membrane (3 µm porosity) of cell capsule cups (Molecular Devices, Sunnyvale, CA). Capsule cups were transferred to sensor chambers where cells were held in close apposition to a silicon sensor within a sensor chamber, which measures small changes in pH in the microvolume of the sensor chamber. Low-buffered medium was pumped continuously across the cells at a rate of approximately 100 ul/min from one of two fluid reservoirs. A selection valve determined which reservoir from which fluid was perfused onto the cells.

The Cytosensor® Microphysiometer generates a voltage signal, which is a linear function of pH, every second. In order to measure acidification rates, flow to the sensor chamber containing the cells was periodically interrupted, allowing for excreted acidic metabolites to build up in the extracellular fluid of the cells. In these experiments, cells were maintained at 37 °C on a two-minute flow cycle with cells being perfused with media for 80 seconds followed by 40 seconds in which the flow of media was stopped. During this 40-second interval, acidification rates were measured for a 30-second interval. In this fashion, a single acidification rate was

calculated every two minutes. The Cytosensor<sup>®</sup> Microphysiometer unit contains eight such sensor units, allowing for eight simultaneous experiments to be performed. Each unit was individually programmed utilizing a computer linked to the system.

GGH<sub>3</sub> cells were initially equilibrated in the low-buffered MEM media for a period of 30-60 minutes in which basal acidification rates (measured as uV/sec), in the absence of any stimuli, were monitored. When the basal rate of acidification changed by less than ten percent over a period of twenty minutes, experiments were initiated. Cells were pretreated for 20 minutes with cell media containing vehicle (1% DMSO) or test compounds at various concentrations (in 1% DMSO final concentration) prior to stimulation with GnRH at various concentrations.

Total Inositol Phosphates Measurement.

Approximately 200,000 GGH<sub>3</sub> cells or 293 cells containing human GnRH receptors were plated onto 24-well tissue culture plates using DMEM media. The following day, cells were loaded with [<sup>3</sup>H] myoinositol (0.5 Ci/ml) for 16-18 hours in inositol-free medium. The medium was aspirated and the cells rinsed with serum-free DMEM. Cells were pretreated with various compounds (dissolved in 1% DMSO final concentration) for 30 minutes and were then stimulated for 45 minutes with GnRH (0.1 nM—1 µM) dissolved in DMEM media in a total volume of 1 mL containing 10 mM LiCl at 37°C. The media was replaced with 1 mL ice-cold 10 mM formic acid, which stopped the reaction and also served to extract cellular lipids. Inositol phosphates were separated by ion-exchange chromatography on Dowex columns, which were washed with 2.5 mL of 10 mM myoinositol and 10 mM formic acid. The columns were then washed with 5 mL of 60 mM sodium formate and 5 mM borax, and total inositol phosphates were eluted with 5 mL of 1 M ammonium formate, 0.1 M formic acid. The column eluates were added to liquid scintillation vials containing 15 ml of scintillation cocktail and were counted by liquid scintillation counting.

Pharmacokinetics and Metabolism:

Pharmacokinetics.

Rats (male or female, 200-225 g) were prepared with indwelling jugular vein cannula as described by Harms et al., *Applied Physiol.* 36:391-398 (1974), and allowed to recover overnight with free access to the standard vivarium chow and water. The compounds were administered to female rats at 5 mg/kg i.v. and 10 mg/kg

p.o. as solutions in 10% DMSO+10% cremophor+80% saline or 10% cremophor+90% saline. The male rats were dosed orally at 50 mg/kg in the vehicles specified in Table 3. The blood samples were withdrawn at specific times, plasma was immediately separated and compound extracted with ethyl acetate. The samples 5 were analyzed by LC-MS using 30-90% gradient of ACN in 50 mM ammonium acetate.

The pharmacokinetic parameters were calculated using WinNonlin software (Scientific Consulting Inc.). The bioavailability was calculated as AUC<sub>p.o.</sub>/AUC<sub>i.v.</sub>, where AUC<sub>p.o.</sub> and AUC i.v. are areas under the plasma concentration-time curve 10 after oral and i.v. administration, respectively.

In vitro metabolism.

Human, rat, dog, and monkey liver microsomes were isolated by differential centrifugation. Specimens of human liver were obtained from the International Institute for the Advancement of Medicine (Scranton, PA). The disappearance of the 15 parent compound was studied in a mixture containing 5 uM compound, 0.5 mg/ml microsomal protein, and 2 mM NADPH in 50 mM K Phosphate buffer, pH 7.4. Samples were incubated for 30 minutes at 37°C. The reaction was terminated by the addition of acetonitrile and compounds analyzed by LC-MS as described above.

In Vivo TestsMaterials and Methods:

Adult male Sprague-Dawley rats were purchased from Harlan Sprague Dawley (San Diego). Animals were housed two per cage and maintained in a 5 temperature-controlled room ( $22 \pm 2^\circ\text{C}$ ) with a photoperiod of 12 hours light/12 hours dark (lights on at 0600 hours). Rat chow (Teklad LM-485 rat diet, Madison, WI) and tap water were provided *ad libitum*.

Animal models to assess activity of GnRH antagonists:Model #1: Castrated Male Rat Model

10 Surgical removal of the gonads removes circulating testosterone and eliminates the negative feedback of testosterone on the hypothalamus. As a result, GnRH is elevated and consequently elevates LH. A GnRH antagonist would be expected to reduce GnRH mediated elevations of LH levels. Antide, a GnRH peptide antagonist, reduces LH levels in castrated rats. The model seems suitable for 15 evaluating small molecule GnRH antagonists.

Male Sprague-Dawley (200-225 g) rats were castrated via the scrotal approach under halothane anesthesia. Animals were allowed 14 days post operative recovery prior to study. Thirteen days following castration, animals were anesthetized with halothane and instrumented with indwelling jugular vein cannula. Details of the 20 cannulation procedure have been described previously (Harms et al., *Applied Physiol.* 36:391-398 (1974)).

On study day, animals were allowed to acclimate to the procedure room while residing in their home cage. Basal blood samples were drawn from all animals. Immediately following basal sampling, vehicle or test compounds were administered 25 by intravenous (iv), intraperitoneal (ip), intramuscular (im) or oral (po) routes. Test compounds were formulated in vehicles specified in Table 3. Blood samples were drawn into heparin containing tubes at multiple time points post treatment. Blood was centrifuged immediately, plasma collected and stored in -20° freezer until assayed. Plasma samples were analyzed using DSL-4600 ACTIVE LH coated-tube 30 immunoradiometric assay kit from Diagnostic Systems Laboratories, Inc. Webster, Texas. Cremophor EL obtained from Sigma, St. Louis, MO.

The results of the GnRH antagonist experiments with various concentrations (1.0-100 mg/kg) in different administration routes (iv, im, and po) of GnRH agents, Compounds C23, and B52 in the above castrated rat model are shown in Figures 1- 4.

Model #2: Intact Male Rat

5        Testosterone is a hormone regulated by the hypothalamic-pituitary-gonadal axis. GnRH is secreted in pulses from the hypothalamus and stimulates the anterior pituitary gland to release gonadotropic hormones LH and FSH. Testosterone is produced when the testes are stimulated by LH. A GnRH antagonist is expected to reduce testosterone levels by inhibiting GnRH stimulation of LH release.

10      Male Sprague-Dawley (250-275 g) rats were single-housed and allowed to acclimate for 1 week prior to study. On study day animals were treated with vehicles specified in Table 3) or test compound. Blood samples were obtained via indwelling jugular vein cannulae implanted 5 days prior to study (Harms et al., *Applied Physiol.* 36:391-398 (1974)). Blood samples were drawn into heparin containing tubes at 15 multiple time points post treatment. Blood was centrifuged immediately, plasma collected and stored in -20° freezer until assayed. Plasma samples were analyzed using DSL-4000 ACTIVE Testosterone coated-tube radioimmunoassay kit from Diagnostic Systems Laboratories, Inc. Webster, TX.

20      The results of the GnRH antagonist experiments with various concentrations (1.0 – 100 mg/kg) in administration routes (iv, im, and po) of GnRH agents, Compounds C23, B3, C2, B52, and B89 in the above intact rat model are shown in Figures 5-10.

Pharmaceutical Compositions

25      The exemplary compounds described above may be formulated into pharmaceutical compositions according to the following general examples.

Parenteral Composition

30      To prepare a parenteral pharmaceutical composition suitable for administration by injection, 100 mg of a water-soluble salt of a compound of the Formula I, II, or III is dissolved in DMSO and then mixed with 10 mL of 0.9% sterile saline. The mixture is incorporated into a dosage unit form suitable for administration by injection.

Oral Composition

To prepare a pharmaceutical composition for oral delivery, 100 mg of a compound of Formula I, II or III is mixed with 750 mg of lactose. The mixture is incorporated into an oral dosage unit for, such as a hard gelatin capsule, which is suitable for oral administration.

5        Intraocular Composition

To prepare a sustained release pharmaceutical composition for intraocular delivery, a compound of Formula I, II or III is suspended in a neutral, isotonic solution of hyaluronic acid (1.5% conc.) in a phosphate buffer (pH 7.4) to form a 1% suspension, which is suitable for intraocular administration.
